프로젝트 주제 및 목표

- 주제 : Offline RL 기반 기업 신용등급 개선정책 학습

- 기업의 재무제표는 한 해의 경영성과 정보를 함축하고 있는 데이터로, 매년 금융기관 및 전문 신용평가사는 재무정보를 기반으로 기업의 신용등급을 측정한다
- 이때, 기업의 올해의 재무제표를 State, 경영활동을 Action, 다음해의 재무제표를 State', 신용등급 변화를 Reward로 본다면 Offline RL 기반으로 기업 경영의 Policy와 그에 따른 성과를 신용등급의 관점에서 평가가 가능하다는 가설을 세울 수 있다

- 목표

- 본 프로젝트의 목표는 기업 경영에 있어서의 절대적인 법칙을 찾는데 있지 않다
다만, Historical Data set에 함축되어 있는 기업의 현실적인 Action distribution을 진단하고 보다 **개선된 Action**을 제안하는데 의의가 있다
- 또한, 실제 현실에서 Counterfactual Action을 취하고 그 결과(S' , R)를 관측하는 것은 불가능하기에 본 Offline RL의 결과물을 **실제에 적용**하는데는 **한계점**이 있을 것으로 추측된다

- **Algorithmic Recourse + Offline RL**

- 자동화된 의사결정 시스템의 결과를 개선하기 위하여 개인에게 실행 가능한 행동을 추천하는 Algorithmic Recourse 연구가 이어졌으며(Karimi et al., 2022), 최근에는 이에 Offline RL 방법론을 적용한 연구 또한 진행되는 추세다(Ceccon et al., 2025).
- 본 연구 또한 기업의 신용등급 개선 Action을 제안하는 **Algorithmic Recourse** 분야에 속하며, **Transformer Encoder** 기반 Representation Learning, **Advanced Weighted Behavior Cloning** + **Implicit Q Learning**을 통해 학습한 Q value를 향상시키는 Action을 제안한다

- **Data Augmentation + Reward Shaping**

- Transition, Reward 등 데이터가 부족한 Offline RL의 한계를 보완하기 위하여 Counterfactual Data Augmentation(Hongye Cao et al., 2025) 등이 시도되었으며, Reward Sparsity를 보완하기 위해 Reward Shaping 기법들이 연구되었다
- 본 연구에서는 데이터의 불균등한 Action distribution 및 Reward Sparsity를 보완하기 위하여 **Financial Simulator** 기반 **Counterfactual Augmentation** 및 **Auxiliary Dense Reward**를 활용하여 Offline RL의 한계점을 개선하고자 한다

방법론

• 개요

- 본 연구는 Evaluation metric인 가상의 신용평가모형(Oracle)을 개발하는 단계와 Offline RL을 통해 신용등급 개선 Policy를 학습하는 단계로 구분된다(Oracle : stage 0 ~ 1, RL : stage 2 ~ 6)
- **Oracle**은 RL 학습단계에서는 참조하지 않는 **Only Evaluation metric**이며, **Offline RL**은 실제 주요 신용평가사가 부여한 **기업 신용등급**과 재무관리 이론에 기반한 **Aux Dense Reward**를 기반으로 학습한다.

• 상세

- **(Oracle)** 신용평가모형 중 전통적인 Score Card 기반 모형(Alpha), Logit Model 구조 모형(beta), ML 기반 XGBoost 모형(Gamma) 3가지 모형을 개발하며, 각 모형은 동일한 변수를 사용한다
- **(Offline RL)** Stage3 Transformer Encoder가 기업의 재무정보를 보고 Representation을 학습하여 전달하고, Stage4 Behavior Clonning은 Historical Data set으로부터 Action을 사전 학습하며, Stage 5 IQL은 Encoder + Behavior Clonning을 출발점으로 삼아 RL 학습을 진행하게 된다

이는 전체 데이터셋(한국 상장사 재무제표 데이터 70,777건) 중 **신용평가사의 신용등급 데이터가 확보된 데이터셋(rated firm-year 4,924건)**이 작아 이를 보완하기 위함이다

방법론 구조도

방법론 - 데이터 수집 및 전처리

• 데이터셋 개요

- 한국 상장사(KOSPI/KOSDAQ/KONEX) 재무제표 70,777건 (폐지사 포함 → 생존편향 완화)
- Temporal Split : Train ~'23년 / Eval '24년. Oracle과 RL 동일한 시간 분할 (미래 데이터 look ahead 방지)

• Oracle 데이터 전처리 과정(Stage0~1)

- (Stage0) Raw 재무제표에서 신용평가사 외부등급 매칭 → 4,924건 rated firm-year 확정
- (Stage1) rated firm-year에 대해 재무비율 산출 및 변수 선정(Alpha, Beta, Gamma 모두 동일 데이터 사용)
 - 모형 학습 : '02~ '19년 2,032건, 시간 외 검증(OOT): '20~'23년 1,790건

• RL 데이터 전처리 과정(Stage2)

- (2A) Raw 재무제표에서 10차원 연속 Action 벡터 추출 (매출성장률, 원가율변화, 부채변동 등)
- (2B) firm_id × fiscal_year 연속 쌍으로 Transition(s, a, s') 구축 + Broad / Rated 분리
 - Broad(전체 상장사, 등급 불필요) → Stage 3 Encoder, Stage 4 BC 학습용
 - Rated(등급보유만, Reward 계산 필요) → Stage 5 IQL 학습용
- (2C) 10D 연속 Action을 11개 이산 후보에 L1 매핑(Candidate Projection) + Dense Reward 계산 및 표준화
- (2D) Rated Transition에 대해 Financial Simulator로 Counterfactual Next-State 생성
 - 관측 3,159 Transition → Counterfactual 34,749 Transition (1:10 증강)

방법론 ① - 신용평가모형(Oracle)

• 구조

- **(Alpha)** NICE평가정보의 홈페이지에 공개된 모형 구조(재무모형 70% + 비재무모형 30%)를 기반으로 설계한 **Score card 모형**이며, **재무모형 6개 변수**(수익성, 안정성, 부채상환능력, 유동성, 활동성, 성장성) 및 **비재무모형 5개 변수**(산업위험, 경영위험, 영업위험, 재무위험, 신뢰도)를 기반으로 하며, 변수 → 표준화 → 구간화 → 단조 변환 → 가중치 최적화 → 등급 Cut-Off 단계로 개발
- **(Beta)** 부도율을 직접 추정하는 **순서형 로지스틱 회귀(Ordered Logit)** 구조이며, 변수 → 표준화 → 로지스틱 회귀 → 임계치 추정 단계로 개발되며, 11개 변수는 Alpha와 동일하게 사용
- **(Gamma)** 트리 앙상블 기반 **XG Boost** 구조이며, 변수 → XG Boost 회귀 → 점수화 → 등급 Cut-Off 매핑 단계로 개발되며, 11개 변수는 Alpha와 동일하게 사용

• 기타

- Data Set은 신용평가사 등급이 있는 rated firm-year 3,822건('02~'23년)이며, Split은 모형 학습 '02 ~ '19년 2,032건, 검증(OOT) '20 ~ '23년 1,790건, **'24년은 Cut-Off임(RL Evaluation에서 사용)**
Stage 0에서 전처리하여 rated firm-year set 확정하고, Stage 1에서 재무모형 및 비재무모형 변수 후보군 데이터셋을 만들고, 변수와 신용등급 간 유의성, 다중공선성 등 고려하여 모형 개발

방법론 ② - Markov Decision Process 정의(Environment 설계)

• Markov Decision Process 정의

- **(State)** 신용평가사의 등급이 존재하는 기업의 T년 시점 재무제표
(단, SSL Encoder에 의해 129개 재무비율 + 2개 범주형 feature 추출 후 256D로 임베딩)
- **(Action)** 기업 경영활동 중 재무적 의사결정이 가능한 10개 재무항목(10D Action Space)을
기반으로, 전략의 일관성 관점에서 구성된 11개 Candidate Action Set.
또한 기업의 재무제표 상 10D 변화를 기준으로 가장 가까운 Action set으로 Pseudo-labeling함
- **(Reward)** 기업의 실제 신용등급 Notch 변화(AAA~D 10개 등급구간 기준)
+ Auxiliary Dense Reward ($\lambda_m \cdot \Delta \text{Merton} + \lambda_f \cdot \Delta \text{FCFF} + \lambda_l \cdot \Delta \text{liquidity}$)
Merton : Merton의 부도예측모형(1974)에 의한 부도거리
FCFF : 기업의 잉여현금흐름으로, DCF법에 의한 기업가치 측정의 척도
Liquidity : 기업이 보유한 현금 유동성(현금 보유 ↓ → 부도 발생 가정)
- **(Transition)** 실측 기업의 신용등급 기반 Transition 데이터는 3,159건이나,
Counterfactual Augmentation 기반 적용 시 모든 Transition에
11개 Action을 취하였을 때 Next State를 Financial Simulator로 생성하여
총 34,749개(=3,159개 × 11개 Action) Transition 생성 가능

방법론 ② - ㉠ 기업 경영활동 Simulation

• Financial Simulator

- Financial Simulator는 기업이 영업하여 현금흐름이 흘러들어와 축적되는 구조에 착안하여, T년 시점 S와 Action을 기반으로 T+1년 시점 S'를 생성
- 다만, 기업의 재무성과는 주요 재무비율(영업이익률, 부채비율 등)로 대표되지만, 실제 재무의사결정자(CFO)가 조절할 수 있는 것은 아니기에, **조절 가능성** 감안하여 **Tier I, II Action Space** 선정
- **(Tier I Action)** CFO가 직접 조절이 가능한 변수군
부채구조 : 단기차입금, 장기차입금, 사채
투자규모 : 유형자산 투자지출
운전자본 : 재고, 매출채권, 매입채무 회전을
- **(Tier II Action)** 기업 경영활동에 따라 간접적 변동
영업활동 : 매출성장률, 매출원가율, 판관비율

• Financial Simulator 구조(회계 항등식 기반)

① T년 시점 재무제표 State

매출 → 원가 → 판관비 → 영업이익

Business Plan(성장률 등)

10D Action(경영의사결정)

② 손익계산서

매출 → 원가 → 판관비 → 영업이익

← (Action) 매출성장, cogs, sga, ppe, 차입

③ 영업 Cash Flow

영업이익 + 감가상각 - 운전자본 변동

← (Action) 재고, 매출채권, 매입채무 회전을

④ 투자 Cash Flow

유형자산 취득/처분 (CAPEX)

← (Action) ppe_pct

⑤ 재무 Cash Flow

차입금 증감 + 사채 발행/상환

← (Action) s_dbt, l_dbt, bond

⑥ B/S Closing(Next State)

기말현금 = 기초현금 + 영업CF + 투자CF + 재무CF

"자산 = 부채 + 자본" 항등식 검증(기말현금 부족 시 차입으로 조달 가정)

방법론 ② - ㉠ 10 Dimension Action Space

구분	차원	의미	예시 (P50 보정 기준)
재무정책 (Tier 1) 기업이 직접 통제 가능	ppe_pct	유형자산 투자 변화율	CX1: -7.4%
	short_debt_pct	단기차입금 변화율	DL1: -24% DL2: -39%
	long_debt_pct	장기차입금 변화율	DL1: -25% RF1: +38%
	bond_pct	사채 변화율	DL1: -33% RF1: +33%
	inv_turnover_chg	재고회전율 변화 (회전수)	WC1: +1.47
	ar_turnover_chg	매출채권회전율 변화 (회전수)	WC1: +1.08
	ap_turnover_chg	매입채무회전율 변화 (회전수)	WC2: -2.26 (지급 연장)
경영계획 (Tier 2) 경영 판단 제약적 변동	revenue_growth	매출 성장률	본 연구에서 0 고정 (시나리오만)
	cogs_ratio_chg	매출원가율 변화 (%p)	OE1: -1.2%p OE2: -2.4%p
	sga_ratio_chg	판관비율 변화 (%p)	OE1: -0.7%p OE2: -1.5%p

각 기업의 한 해 경영활동을 10개 차원의 연속 벡터로 표현하며, 후보별 크기는 Historical Data 관측 중앙값(50%) 기준으로 보정된다.
P50 = Action Space별 관측된 기업 행동의 절대값 기준 중앙값. 이론적 최대(ACTION_BOUNDS)가 아닌 현실적 행동 크기.

방법론 ② - ㉔ 11 Candidate Action set

행동군	ID	ppe	inv	ar	ap	s_dbt	l_dbt	bnd	rev	cogs	sga	요약
Noop	A0	—	—	—	—	—	—	—	—	—	—	기준선
부채 축소	DL1	—	—	—	—	-24%p	-25%p	-33%p	—	—	—	소폭
	DL2	—	—	—	—	-39%p	-50%p	-50%p	—	—	—	중폭
차환	RF1	—	—	—	—	-29%p	+38%p	+33%p	—	—	—	단기→장기
Capex· WC	CX1	-7.4%p	—	—	—	—	—	—	—	—	—	설비투자 ↓
	WC1	—	+1.47	+1.08	—	—	—	—	—	—	—	운전자본 압축
WC+AP	WC2	—	+1.47	+1.08	-2.26	—	—	—	—	—	—	WC1+지급연장
비용 효율	OE1	—	—	—	—	—	—	—	—	-1.2%p	-0.7%p	소폭 절감
	OE2	—	—	—	—	—	—	—	—	-2.4%p	-1.5%p	중폭 절감
혼합	MX1	—	—	—	—	-24%p	—	—	—	-1.2%p	-0.7%p	비용+부채 ↓
	MX2	—	+1.47	+1.08	-1.13	-24%p	—	—	—	—	—	유동성 확보

10D Action Space를 기반으로, 전략정 방향성이 일관적인 그룹을 묶어 11개 Candidate Action set을 생성하였음

이는 10D Continuous Action Space로 직접 IQL을 학습하였을 때, RL이 학습한 Policy가 의미론적으로 일관성이 떨어졌기 때문.

따라서 Heuristic 반영하여 Action set 구성하였으며, 이 중 long_debt_pct 와 bond_pct는 historical 변동폭이 너무 커 최대값으로 clip되었음

방법론 ③ - Offline RL 알고리즘

• Stage 3 : Self-Supervised Encoder (Transformer, d=256)

- 129개 재무비율을 각각 독립 토큰으로 변환
- 132개 토큰 시퀀스 → 4-layer Transformer
→ CLS 토큰 = 256차원 임베딩
- SSL 목적함수 : Loss = MCM + 0.5·ACD + 0.3·Contrastive

• Stage 4 : Class & Family Balanced Behavior Cloning

- Encoder를 통해 관측된 행동 모방 (Soft Target, Broad 데이터 input)
- Class Balance : 희소 후보(MX2, RF1) 가중 + Family Balance(균형)
- BC는 IQL Actor의 출발점이며, BC가 특정 행동을 누락하면 IQL도 선택 불가(OOD)

• Stage 5 : Candidate-IQL

- Stage 4 Encoder+BC를 초기값으로, Critic/Value/Actor를 동시 학습
- Twin-Q Critic : target = $r + \gamma(1 - done) \cdot V(s')$, Smooth L1
- Expectile Value : $\tau = 0.85$ 비대칭 regression → Implicit Max 추출
- AWR Actor : $\exp(\beta \cdot advantage) \times CE(logits, a) \rightarrow Advantage$ 가중
- Cross-Attention Critic Head : Firm-State × 후보 간 Attention
- q_pareto_knee Checkpoint : $Q \leftrightarrow Entropy$ Pareto Frontier 최적화
- 학습 데이터 : Rated만 (~'23 Train Set)
- 평가 : 실측값 Observed(3,159) 또는 Counterfactual 증강(34,749)

방법론 ④ - Evaluation metric

- **Stage 6 : Oracle based RL Evaluation**

- Oracle($\alpha/\beta/\gamma$)은 RL 학습 단계에서 일절 참조하지 않는 only evaluation metric (Information Barrier)
- Stage 5까지 학습 완료된 정책을 2024년 재무제표에 State 적용하여, Financial Simulator로 Next State 생성
- 평가 대상 : 2024년 575 firm $\times$ 각 정책의 행동 $\rightarrow$ Financial Simulator $\rightarrow$ Oracle 채점 $\rightarrow$ 신용등급 평점 변화
- **α (Isotonic Scorecard)** : 변수별 단조 보정(isotonic regression) $\rightarrow$ 가중합 $\rightarrow$ R_score $\rightarrow$ 등급
- **β (Ordered Logit)** : 순서형 로지스틱 회귀로 부도율 직접 추정 $\rightarrow$ 임계치 기반 등급 부여
- **γ (XGBoost)** : 트리 앙상블 회귀 $\rightarrow$ 점수화 $\rightarrow$ 등급 매핑

- **RL과 비교 대상 정책**

- **C0_noop** : **No Action**, 2024년 State에서 아무런 Action을 하지 않고 Next State 생성하여 Oracle로 평가
- **C2_weakest_component_rule** : Oracle 변수 11개 중 **평가점수가 가장 낮은 재무항목**을 선택하여, 해당 항목을 개선하는 Rule-based Heuristic (Oracle 구조 기반)
- **C3_candidate_iql** : IQL이 학습한 Policy에서 **Q 값**과 **Action distribution entropy**를 Pareto 최적화 하는 Epoch을 선정
- C3 변형 : q_{argmax} (Q만 최대화), $q_{\text{rerank_at_k}}$ (상위 k개 Policy 중 Q값이 높은 것 재선택, $k=3,5,7,9$)
- **Only Single Action** : 11개 Action 후보 중 1개를 **모든 firm에 동일하게 적용**했을 경우 (DL2, OE2, MX2, OE1 등)

실험환경

• 실험장비

- 장비 모델명 : Lenovo LOQ 15ARP9 노트북
- 프로세서 : AMD Ryzen 7 7435HS(3.10 GHz), RAM 24.0GB(4800 MT/s)
- 그래픽카드 : **NVIDIA GeForce RTX 4060 Laptop GPU (8GB of GDDR6 VRAM)**

• 소프트웨어 환경

- 운영체제 : Windows 11
- 개발환경 : Python 3.12 가상환경(.venv), Windows PowerShell, VS Code
- 주요 라이브러리 : PyTorch(2.6.0+cu124), CUDA(12.4) pandas(3.0.3), numpy(2.4.6), scikit-learn(1.9.0),
scipy, statsmodels, pyarrow
- GPU 학습 : PyTorch CUDA backend 사용

• 실행 및 재현조건

- 프로젝트 경로 : C:\Users\UserName\Desktop\WRL_repo
- 주요 실행 스크립트 : run_oracle_stage0_stage1.ps1, run_rl_unified_stage3456.ps1
- Deterministic(No seed) : Stage 0 ~ 2(데이터 전처리), Stage 6(Eval) / **Stochastic(Seed) : Stage 3 ~ 5(RL)**
- Oracle 및 데이터 전처리 단계는 CPU 중심, Stage3~5 RL 학습은 GPU 중심으로 수행

실험결과 – Key Findings

• 데이터와 Offline RL의 구조적 한계

데이터 · 레이블

- ① 실제 기업 action 관측 불가
→ **pseudo action labeling** 사용
- ② 외부 신용등급 보유 데이터 희소
(rated $\approx$ 4천 / transition $\approx$ 3천)
- ③ 등급이 실제로 변한 transition은 약 18%뿐

Action 구조

- ④ 재무제표만으로 firm별 알맞은 action 선택이 어려움 (firm-curated)
- ⑤ 11개 candidate에 명확한 우열
→ **단일 action(DL2)이 상당히 강함**
- ⑥ Oracle이 선호하는 action(DL2·MX2)은 historical 관측엔 희소함 → **Counterfactual**
- ⑦ Offline RL은 Out-of-Data action 학습이 본질적으로 어려움

Reward 신호

- ⑧ Base reward(등급 notch Δ)는 너무 희소
→ agent가 action을 학습하기 어려움
(등급변화 567T, 상향 291, 하향 276)
- ⑨ Dense aux reward가 필요하나, 평가자(Oracle)를 직접 참조해선 안 됨

데이터 출처 (data provenance)

파일 / 위치	행수	이 자료에서의 용도
multi_oracle_policy_eval.parquet (각 run/outputs/stage6_multi_oracle_eval/)	10,350 =575×18	정책별·firm별 Oracle $\alpha/\beta/\gamma$ 점수와 Δ noop (T1·T3·T4·T5·T6·T7)
phase1_pretrain_candidate.parquet col = projected_candidate_id	38,190	관측 행동 pseudo-label 분포(broad) = C_obs 가중치 (T2·T3)
phase3_iql_candidate.parquet col = reward_raw_notch / reward_aux_*	3,159 (dev1584/ooot1575)	rated transition의 base-aux reward 분포·통계 (T8a)
phase3_iql_counterfactual_candidate_P50.parquet col = candidate_id / delta_*_capacity	34,749 =3,159×11	행동별 capacity Δ = aux 성분 기전 (T8b)
run 디렉토리 × 7 seed (rl_unified_...{s1..s5,s3a,s3b})	—	멀티시드 안정성 (T7)

실험결과 – Key Findings (Framework)

• 희소성을 극복하기 위한 설계

- Rated Transition이 3,159개로 적고, 그 중 Reward가 발생하는 Transition은 567개에 불과하여 적은 데이터로 RL Agent를 학습시킬만한 설계 필요
- **(Multi layer 사전학습)** 70,777건의 풍부한 Unrated Broad 데이터셋을 활용하여 Encoder로 Representation을, Behavior Cloning으로 기업의 Historical Action을 사전학습한 후, **Rated 데이터셋 3,159건으로 IQL을 최종학습**하는 방안 채택
- **(Auxiliary Reward)** 신용등급 변화라는 Base Reward는 567건으로 희소하기에 전체 Transition의 80% 이상이 무보상이며, 따라서 **Merton**의 부도 모형, 기업가치(DCF)의 기초인 **FCFF**, 그리고 **Liquidity**를 보조로 사용하여 Reward Sparsity 해소
- **(Semantic Alignment)** 10D Continuous Action Space를 RL이 직접 학습하면 전략적으로 일관된 Policy를 학습 못하는 단점이 있어, Heuristic 기반 **11개 Candidate Action set** 설정하고 RL이 선택할 수 있게 하여 전략적 일관성 강화

실험결과 – Key Findings (Pseudo Action Labeling & BC)

- 기업의 Historical Action의 한계점 극복 필요
 - 본 Offline RL의 Pseudo Action Labeling 및 Behavior Cloning은 본질적으로 기업의 Historical Action을 모방하도록 설계되었으나, **Historical Action은 Oracle Alpha 상 가치가 낮은 Action(CX1, WC1 등)의 비중이 크다**는 단점이 있다

관측된 기업 행동 분포(C_obs)

$C_{obs} = \sum_a p_{obs}(a) \cdot mean_Anoop(a)$ | p_{obs} : projected_candidate_id 빈도($n=38,190$) · $Anoop$: T1 단일행동값($n=575$)

행동	count	p_obs	α Anoop	α 기여	β Anoop	β 기여	γ Anoop	γ 기여
A0 (noop)	3,436	0.0900	+0.0000	+0.00000	+0.0000	+0.00000	+0.0000	+0.00000

DL2	753	0.0197	+0.5199	+0.01025	+0.0440	+0.00087	+0.5840	+0.01152
RF1	2,370	0.0621	+0.1241	+0.00770	+0.0138	+0.00086	+0.1593	+0.00989
CX1	10,954	0.2868	+0.2002	+0.05742	+0.0128	+0.00366	+0.1864	+0.05347
WC1	6,270	0.1642	+0.3068	+0.05036	+0.0184	+0.00303	+0.2690	+0.04416
WC2	3,015	0.0789	+0.4795	+0.03785	-0.0140	-0.00111	+0.4164	+0.03287
OE1	4,099	0.1073	+0.3064	+0.03288	+0.0889	+0.00954	+0.1744	+0.01871
OE2	3,745	0.0981	+0.5700	+0.05589	+0.1764	+0.01730	+0.3728	+0.03656
MX1	955	0.0250	+0.5003	+0.01251	+0.1091	+0.00273	+0.4389	+0.01097
MX2	693	0.0181	+0.6013	+0.01091	+0.0240	+0.00044	+0.5665	+0.01028
$\Sigma = C_{obs}$	38,190	1.000		+0.28962		+0.03855		+0.24554

검증 $C_{obs}(\alpha)=+0.290(broad)$ vs $C3(\alpha)=+0.612 \rightarrow 2.11\times$. 리포트의 CX1 31.1%는 rated 분포(31.9%)와 일치 — 리포트는 rated 기준, 본 표는 broad(28.7%) 기준. 둘 다 $C_{obs}\approx+0.29\sim0.32$.

실험결과 – Key Findings (Action Labeling & BC 분포 교정)

• Low value Action 편중 완화 Solution : L1 Projection · Class Balance · Family Balance

– Offline RL은 BC distribution 외의 행동을 학습하기 어려움. BC의 Low value Action 편중(CX1 28.7%·WC1 16.4%) 때문에 BC→IQL의 CX1 Action 비중이 높아지므로, **고가치 희소행동(DL2·MX2)**을 BC distribution에서 **보존**해야 한다

① L1 Projection

(active-intent 가중)

10D 연속 action을 의미축에 가중치를 준 L1로 후보에 매핑. 단순 L1은 애매한 행동을 noop으로 흘러보내지만, active-intent는 의도를 살려 올바른 후보로 레이블링.

효과 - noop sink 회수

② Class Balance

($\beta=0.999$, effective number)

빈도에 따라 역으로 가중치 적용. **흔한 저가치 Action** 가중치↓, **희소·고가치 후보는 가중치↑** → BC가 희소행동을 누락하지 않도록 유도하는 장치

효과 - 표본 가중치

③ Family Balance

(p=0.5 blend)

11개 행동을 6개 family(부채·차환·Capex/WC·비용·혼합·noop)로 묶어 **family 단위로 분포를 균형화**함 → 한 계열이 Action distribution을 독점하는 것을 방지

효과 - family 분포

종합 효과 — 관측 분포 → BC 사전분포 교정 → C3(RL) 최종 분포

행동	Oracle α 가치	관측 비중 (BC 타겟)	3-Lever 효과	C3(RL) 최종 비중	해석
CX1	저 (+0.20)	28.7% (최다)	CB x0.79 ↓ · family ↓	0%	저가치·고빈도 Action → 제거됨
WC1	중 (+0.31)	16.4%	CB x0.79 ↓ · family ↓	18.6%	억제되나 일부 잔존
DL2	고 (+0.52)	2.0% (희소)	CB x1.49 ↑ · family ↑	29.7%	고가치·저빈도 → 보존·증폭
OE2	고 (+0.57)	9.8%	CB x0.81 (유지)	36.2%	고가치 → RL이 주력 채택

핵심 3-Lever는 BC 사전분포를 교정해 '저가치 CX1 collapse'를 막고 고가치 희소행동을 살린다. 최종 비중은 그 위에서 IQL의 Q값(보상)이 결정
레버는 필요조건(없으면 IQL이 CX1에 갇힘), 분포 다양화는 보상·HP가 마무리. C3 분포는 s1 기준(seed별 상이).

실험결과 – Key Findings (Encoder)

- **Encoder의 학습 정도 ≠ 기업의 재무정보 Representation**
 - 본 실험에서 SSL Encoder의 목적함수로 MCM, ACD, Contrastive를 설정하였으나, 해당 목적함수가 “**기업별 알맞은 Action을 고르기 위한 재무정보**”와는 차이가 있었던 것으로 보인다(Encoder는 RL Reward로 학습 X)
 - Batch와 Epoch을 늘려 학습하면 Train Loss는 떨어졌으나 IQL이 성능이 하향되는 추세를 보였고, Epoch을 15까지 줄이면 성능은 향상되었으나 Multi seed 안정성이 훼손되었다
 - 따라서 Encoder는 중간 수준인 **Batch 512, Epoch 30** 선에서 fix하고 다음 단계 진행하였다

Encoder 목적함수

$$\mathcal{L} = 1.0 \mathcal{L}_{\text{MCM}} + 0.5 \mathcal{L}_{\text{ACD}} + 0.3 \mathcal{L}_{\text{Con}}$$

Encoder Sweep

Encoder 설정	best val_loss	IQL 성능 경향
B512 · Epoch 15	1.6641 (최악)	성능 ↑ (높음)
B512 · Epoch 30 ← 채택	1.3815	균형 (안정적)
B256 · Epoch 50	1.2201	성능 ↓
B256 · Epoch 49 (s42)	1.1325 (최저)	성능 ↓ (낮음)

loss가 낮을수록 IQL 성능이 낮은 **역상관 관계** (Epoch 15 > 30 > 50).

Explanation

(Representation) Encoder의 학습은 **기업별 알맞은 Action** 결정하는 **Firm aware information**과 정렬되지 않는다. 과적합된 Encoder는 IQL이 사용하기 어려운 방향으로 firm 정보를 압축한다.

(Epoch 15) 성능은 가장 좋았으나 **multi-seed별 편차 과도**하여 사용 어려우며 재현성을 위해 Batch 512 · Epoch 30을 선택함

(Cross-Attention critic head) 표현 전달을 늘리려 Linear Head에서 교체하였으나 sparse reward에선 오히려 성능 하락하였음. 단, **Dense Aux Reward 도입 후엔 정상 작동함**(Finding 5).

실험결과 – Key Findings (IQL Critic & Actor)

• Critic & Actor의 학습과 안정성 사이의 절충

- 본래 IQL은 Critic이 Offline Data set에서 Q와 V를 학습하고 Actor는 Critic이 높게 평가한 Action을 Advantage 기반으로 학습하지만, 본 실험에서 **Critic과 Actor가 학습한 Policy에 간극이 큰 문제**가 있었다
- 따라서 Advantage 외에도 **Distillation 항을 추가**하여 Actor가 직접 Critic Policy를 모방할 수 있도록 하였으며, Critic의 Head를 Linear Head에서 **Cross Attention Head**로 변경하여 Encoder가 학습한 기업의 재무정보에 관한 Non linear Representation을 잘 캐치할 수 있도록 설계하였다

IQL의 Critic은 신용등급을 개선하는 가치(Q, V)를 학습했으나, Actor는 epoch을 늘려도 그 정책을 재현하지 못함(Stage 5 Epoch 80 ~ 150)

진단 Actor가 Critic이 평가한 고가치 행동을 정책으로 옮기지 못함 → **Critic→Actor Distillation (CE, $\lambda=1.5$)** 추가.
Distill을 키우자 Actor가 Critic 정책을 잘 흡수하였으나, 지나치게 Distill이 커지면 Action distributio이 Single Action으로 Collapse 하였음

BC에 갇히면 안 되는 이유

BC 분포는 저가치 행동(CX1) 중심. Actor가 BC를 그대로 복제하면 Oracle 가치가 낮은 정책에 머문다

BC에서 너무 멀어지면 안 되는 이유

distill이 과하면 단일 action으로 collapse(데이터 분포 이탈 = OOD).
Offline RL은 데이터 밖 행동의 가치를 신뢰할 수 없으므로, BC 근방에 머물며 그 안에서 개선해야 한다.

실험결과 – Key Findings (Base & Aux Reward)

• Sparse Baseline Reward 와 Dense Auxilliary Reward의 상관관계

– Baseline Reward는 전체 Transition 중 17.9%(567건)에만 신용등급 변화가 있어 학습이 어려우며, 따라서 기업 재무관리 분야에서 이론적 배경을 가진 **Merton, FCFF, Liquidity** 항을 Aux Reward로 사용하기로 하였다

Auxiliary Reward 상세

항	측정량 (시점 t) — 코드 확정	Δ (변화)	scale: clip(Δ/s , $\pm cap$)	Λ (최종)
Merton*	$b = D / \text{총자산}$, $D = \text{단기차입} + \frac{1}{2} \cdot \text{장기차입} + \text{회사채}$ (KMV 부도점)	$\Delta_M = b_t - b_(t+H)$	$s = 0.171 \text{ (p95} \Delta), \pm 1.0$	0.05
FCFF	$c_F = (\text{영업CF} - \text{CapEx}) / \text{총자산}$	$\Delta_F = c_F(t+H) - c_F(t)$	$s = 0.249 \text{ (p95} \Delta), \pm 0.5$	0.45
Liquidity	$c_L = (\text{현금} + \text{단기투자}) / \text{총자산}$	$\Delta_L = c_L(t+H) - c_L(t)$	$s = 0.178 \text{ (p95} \Delta), \pm 0.5$	0.45
Base	rating_num (신용등급 notch)	$r_base = \text{rating_num}(t) - \text{rating_num}(t+H)$, 정수 (-7...+6)	- (이산, scale 없음)	—

* Merton 모형은 본래 수식에 부도율(PD)을 사용하나, Raw Data에서 부도율 측정 불가능하여 본 실험은 KMV 모형에 따른 부도점을 Proxy 변수로 사용하였음

Reward 성분 통계 (n=3,159)

성분 (컬럼)	mean	std	λ
reward_raw_notch (base)	-0.0003	0.5995	—

reward_train (표준화)	-0.0018	0.9862	—

Aux ↔ Baseline Reward 간 상관관계 (n=3,159)

성분	Pearson r	p-value
Merton	-0.0090	0.6148
FCFF	-0.0123	0.4897
Liquidity	+0.0177	0.3191

실험결과 – Key Findings (Aux Reward & Actor’s learned Policy)

- **Dense Auxilliary Reward이 IQL Actor에 미치는 영향**
 - Aux Reward 중 **Merton 부도거리** 항은 IQL Actor가 학습하는 Action distribution 중 **DL2(강한 부채감소)에 크게 보상하는** 경향이 있었으며, DL2는 Oracle Alpha 점수 개선효과가 크기 때문에 **Actor의 성능을 개선시키는** 효과가 있었다
 - 그러나 **Merton** 항의 영향이 너무 크기 때문에 **가중치(λ_M)를 최소화**하고 **Liquidity** 항의 **가중치(λ_L)를 높여**, Agent가 기업이 보유한 현금으로 부채를 축소하려는 유인을 견제하는 방향으로 학습 진행하였다

Aux Reward가 IQL Actor의 Action distribution에 미치는 영향

행동	$\Delta merton$ (부도거리, +=개선)	$\Delta fcff$ (잉여현금)	$\Delta liquidity$ (현금, +=보유 ↑)	Oracle $\alpha\Delta$ (Evaluator)

37 ★	0.05	0.45	0.45	DL2 56% (균형·채택)	+0.12

실험결과 – Key Findings (Counterfactual Augmentation)

- Counterfactual Transition Augmentation – Historical Action의 가치-빈도 역전을 All Action 균등화로 교정
 - Aux Reward 이후 Actor는 C2(Weakest improvement)를 따라잡았지만, Counterfactual 적용 이후 C2를 큰 격차로 추월하기 시작하며, 가장 Value가 높은 Single Action(MX2, DL2, OE2 등) 이상으로 성능 향상되었다
 - 기존 Offline RL은 Transition 당 학습 가능한 Action이 하나로 제한되지만, Counterfactual은 모든 Transition에 11개 Action 모두 증강함으로써 학습 가능한 신호를 늘린다. 다만 실질적으로 Contextual Bandit에 가까워지는 단점이 있다

Counterfactual Augmentation이 고가치 Action(MX2, OE2, DL2) 학습에 미치는 영향

행동	관측 빈도(BC) (n=3,159)	관측 비중 (%)	Counterfactual Aug. (전 행동 균등)	학습 reward (train)	Oracle $\alpha\Delta$ (Evaluator)
MX2	63	2.0	3,159	0.617	+0.601

실험결과 – Key Findings (Pareto Knee Checkpoint Selection)

- Pareto selection – 정책가치 Q와 Action 다양성 Entropy가 균형을 이루는 Frontier에서 Checkpoint 생성
 - 이전의 Max Q selection은 Critic Q를 최대화하는 방식으로 Action 불균형이 강하였으나, 31번 실험부터 적용된 Pareto knee(Q 체감 시작점) selection은 Q를 5%만 양보(0.662 → 0.629)하며 11개 Action 모두 살렸음
 - 본 실험에서는 Pareto selection 구현을 간단화하기 위하여 정규화 후 최소목적 최대화 방식으로 구현되었으며, 이는 정규화 공간에서 이상점 (1, 1)까지 L_∞ (Chebyshev) 거리가 최소인 Frontier 상 점을 고르는 것이다 ($\operatorname{argmax} \min(q_norm, e_norm) = \operatorname{argmin} \max(1-q_norm, 1-e_norm)$ (이상점 L_∞ -Chebyshev 거리))

argmax 행동분포 — max-Q vs knee

행동	max-Q (ep32)	Pareto knee (ep75)
OE2	25.3	39.3
MX1	22.3	24.3
DL2	35.3	17.0
RF1	5.8	8.5
WC1	0.0 (drop)	3.8
CX1	0.0 (drop)	2.5
MX2	10.1	2.0
DL1	0.0 (drop)	0.9
OE1	0.0 (drop)	0.8
WC2	1.1	0.8
A0	0.0 (drop)	0.2

실험결과 – Key Findings (Hyperparameter 확정, Multi seed run)

- **M 0.05, F 0.45, L 0.45 Couterfactual Pareto selection 조합 확정** – 성능은 안정적, Action distributio은 편차 존재
 - 확정된 Hyperparameter 조합은 seed에 따라 Action distribution이 계속 바뀌는 등 편차가 있었으나, Actor가 고르는 Major Action은 DL2, OE2, MX2 등 Oracle Alpha 기준 고가치 Action이었으며 **전체 성능은 C2 대비 높게 유지되었다**
 - IQL Actor가 학습하는 Policy가 seed에 따라 변하는 것은 **Encoder가 학습하는 Representation, BC가 학습하는 Historical Action, IQL의 Critic이 학습하는 Policy** 모두 달라져 영향을 받기 때문인 것으로 보인다((1/2/2) & (2/1/1) run 교호작용)

Aux Reward 확정 조합(M 0.05 F 0.45 L 0.45)의 Multi seed run

실험결과 – Key Findings (최종실험 RL > C2 > C_obs)

- 최종 확정된 RL 결과는 C2, C_obs 보다 좋다
 - IQL Actor는 C2 Heuristic (Oracle 상 약점 개선), C_obs (기업의 실제 Historical Behavior) 보다 좋은 결과를 보이며, 이는 기업이 실제로는 CX1(28.7%), WC1(16.4%) 등 신용평가모형(Oracle) 상 낮은 가치의 행동 비중이 높았기 때문으로 어찌면 **실제 기업은 RL과 달리 경영여건 상 취할 수 있는 Action의 폭에 제약**이 있다고 해석할 여지도 있다
 - 다만, RL은 Oracle Beta에서는 C2에 근소하게 뒤지는 결과를 보이는데 이는 Oracle Alpha, Beta, Gamma가 동일한 11개 변수를 사용함에도 각각 구조와 가중치가 다르며, Beta에서는 Alpha와 달리 비용효율적인 Action(OE2, MX1, OE1)의 Score 효과가 높기 때문이다

동일 575 firm · 동일 Oracle α 채점. C_obs = 기업의 실제 관측 행동분포를 그대로 적용했을 때의 기대 점수

이론 상한(firm별 최적 = +1.1306) 대비 포착률 · Oracle α

β backend에서는 C2가 C3보다 근소 우위(α·γ는 C3 우위). C_obs는 세 backend 모두에서 최하위.

이론 상한 (firm별 최적행동) 대비 C3, C2, C_obs 성과

Oracle	ceiling Δnoop	C3 / 천장	C2 / 천장	C_obs / 천장
α	+1.1306	54.1%	44.7%	25.6%
β	+0.1774	59.1%	76.0%	21.7%
γ	+0.9705	51.4%	41.4%	25.3%

실험결과 – Key Findings (최종 Offline RL 성능)

- 그러나 최종 Offline RL은 썩 좋지도, 나쁘지도 않다
 - 전체 기업 중 58.6%에서는 최적의 Action이 2개 이상이며, 11개 모두 최적은 15.1%, No Action이 최적인건 17.9%이었다 이는 Oracle Alpha의 Score가 평가항목별 50개 구간으로 나뉘어 산출되기 때문에, 동일구간에서는 Score 변화가 없기 때문 (전통적 Score Card 모형의 특징)
 - RL이 정확한 최적 행동을 맞힌건 13.0%, 최적은 아니지만 Score가 유사한 것은 45.7%, State별 Top3 Action을 맞힌건 77.4%로, RL은 평가기준에 따라 성능이 좋다고도 나쁘다고도 평가할 여지가 있다

기업별 최적행동 현황

지표	firm 수	%	정의

토의 및 결론- 실험결과에대한생각- 보완및개선사항

• 성과 및 Contribution

- 적은 규모의 Data set, Sparse Reward, Offline RL의 OOD 한계 등을 Encoder + BC + Counterfactual + IQL로 극복한 것은 해당 실험의 성과라고 생각된다
- 기업의 재무제표로부터 Behavior Cloning으로 Historical Behavior 패턴을 추출하고, 가상의 신용평가모형(Oracle)을 개발 하였으며, Financial Simulator를 통해 Counterfactual RL을 시도할 환경을 구축한 점 또한 성과라고 생각된다
- C2 및 Single best Action(DL2, 강한 부채축소)은 의미상 강한 Heuristic인데 이를 RL이 뛰어넘는 성능을 달성한 것 또한 성과라고 생각된다

• 보완 및 개선사항

- 이번 실험에서 다룬 Action은 오직 재무관리 관점의 의사결정 뿐이었지만, 실제 경영환경에서 재무 의사결정은 사업계획에 의존적이기에 재무 의사결정 만으로 신용등급 개선이 가능하다고 주장하기에는 무리가 있다
- Financial Simulator의 Business Plan 기능은 실제 경영환경의 어려움(ex. 매출증가 하려면 CAPEX, 마케팅비용 등을 늘리는 Trade-off 존재)을 반영하지 못한다는 한계점이 있으며, 이를 개선하면 더욱 유용한 결과 도출 가능할 것이라 생각된다
- M&A, 물적분할, SPC 설립 등 기업의 구조적 변화를 수반하는 의사결정을 검토하지 못한다. 이를 가능하게 하기 위해서는 Oracle의 약한 비재무 평가모형과 Financial Simulator 기능이 강화되어야 가능할 것으로 판단된다
- RL이 기업별 특성 정보를 학습하여 알맞은 Action을 선택하는 Policy 학습이 약하였다. Encoder 학습 시 목적함수 변경, 혹은 구조적 변화가 있어야 성능 개선할 수 있을 것으로 추측된다

best val_loss 비교

진단

- Encoder가 학습하는 Representation은 IQL 단계에서 Critic 및 Actor가 선택하는 Action의 종류에 지대한 영향을 미침
- 그러나 학습이 잘된(loss ↓) Encoder가 무조건 우수한 IQL 성능으로 이어지는 것은 아님. 오히려 Epoch이 낮아질수록 성능이 증가(Epoch 15 > 30 > 50)
- Batch 256 대비 512가 다소 안정적인 것으로 보이며, Epoch 15는 multi-seed 안정성이 떨어져 **Batch 512 epoch 30 Encoder**를 최종 선택하였음

※ Oracle을 재개발하는 과정에서(R136 제외) 데이터셋이 변경되며 2024년 Eval firm 모수 변경(421 → 575)
R136(매입채무/유동부채) 제외사유 : 매입채무가 증가할수록(지급을 늦게할수록) 신용등급이 좋아지게 되기 때문

Stage 5 C3(Actor) 행동 분포(%)

Stage 6 평가 결과 - Oracle α Δ noop

최종 실험 – 43) Stage 3 seed 1 / Stage 4 ~ 5 seed 2

Hyperparameter

Stage	항목	값
2	Reward	$\rho=0$ $M=0.05$ $F=0.45$ $L=0.45$
2-4	Mode	S2:skip / S4:train
3	Encoder	skip (30ep) / seed 1
4	CB / FB	$\beta=0.999$ / $p=0.5$ / seed 2
5	$\gamma/\tau/\beta$	0.6 / 0.85 / 15 / seed 2
5	Distill / Critic / selec	$\lambda=1.5$ / cross_attention / pareto
5-6	S5 / Eval	train (lr=0.0001) / 575

Stage 3 Loss (30ep)

Stage 4 Loss (80ep)

Stage 5 Loss (80ep)

Stage 4 BC 행동 분포(%)

Stage 5 C3(Actor) 행동 분포(%)

Stage 6 평가 결과 - Oracle α Δ noop

최종 실험 – 44) Stage 3 seed 2 / Stage 4 ~ 5 seed 1

Hyperparameter
